

ABSTRACT OF THE DISCLOSURE

5 An improved pallet made of a synthetic resin wherein the underside
of the upper deck is substantially planar, and the supports which separate the upper
and lower decks are integrally formed with and project upwardly from the lower
deck, and are secured to the underside of the upper deck. The upper ends of the
supports are received in recesses in the underside of the upper deck, and the recesses
and the supports preferably have mating elements which snap-actingly engage one
10 another to lock the supports in the recesses when the decks are assembled.
Preferably, the supports are tapered, the lower ends of the supports being wider than
the upper ends thereof. Top surface of the upper deck, the bottom surface of the
lower deck, and the underside of the upper deck in the fork-receiving regions
between the supports may have a slip-resistant scuffed texture.
